Arbitrage?

Problem ID: arbitrage
CPU Time limit: 3 secon
Memory limit: 1024 MB
Difficulty: 3.6

Source: CTU Open 2010

If you are going to travel to the World Finals, you cannot rely on Czech Crowns. You would have to exchange your money for various foreign currencies. This problem deals with multiple currencies and their exchange rates. Your task is to verify that some set of exchange rates is safe, namely detect a possibility of so-called arbitrage.

An *arbitrage* is a risk-free combination of buy and sell operations that gains profit from imbalance in market prices. The prices may apply to various things, typically stock exchange but also currencies.

Input

The input consists of several test cases. Each case begins with a line containing one positive integer number C, $1 \leq C \leq 200$, the number of currencies.

The second line of each test case contains C currency codes separated by a space. Each code is composed of 3 uppercase letters and all codes in one test case are different.

The third line contains one integer number $R, 0 \leq R \leq C \cdot (C-1)$, the number of exchange rates available. Each of the following R lines contains one exchange rate in the following format: first currency code, space, second currency code, space, integer number A_i, colon (':'), and integer number B_i. The meaning is as follows: If you pay A_i units of the first currency, you will get B_i units of the second currency. You may assume that $1 \leq A_i, B_i \leq 100$ and that the two currencies are different.

The last test case is followed by a line with $C = 0$.

Output

For each test case, print one line of output. If there exists any possible sequence of currency exchange operations that would result in a profit, the line should contain the word "`Arbitrage`". Otherwise, simply print "`Ok`".

The word *profit* in this case means that you start with any amount of any currency and after performing any number of exchanges you will have strictly higher amount of the same currency.
